Financial, Operational & Risk Performance Analysis

A Power BI portfolio project | Power BI · Power Query · DAX

Project at a glance

I built this three-page Power BI report to explore how financial results, system performance, and risk indicators can be monitored together. Using an IoT financial management practice dataset, I wanted to go beyond displaying totals and create a dashboard that makes comparisons between regions and departments easy to understand.

The business question

A healthy revenue figure does not tell the whole story. Decision-makers also need to understand profitability, operating costs, technical performance, and potential risk. My dashboard brings those views into one place and addresses a practical question: where is performance strongest, and which areas deserve a closer look?

How I approached the analysis

- Imported and reviewed the dataset in Power BI, using Power Query to prepare it for analysis.
- Built financial measures in DAX, including Net Profit Margin and Operating Cost Ratio.
- Used averages for scores and performance rates, and sums for count-based indicators such as security breach attempts.
- Created interactive charts and KPI cards to compare results across regions and departments.
- Checked the calculation methods and used the findings to develop follow-up questions and recommendations.

1 | Financial Performance Overview

The financial page focuses on revenue, net profit, and operating costs, with regional comparisons to show where results differ.

Metric	Dashboard value
Total Revenue	4.67 billion
Total Net Profit	1.36 billion
Total Operating Cost	2.29 billion
Net Profit Margin	29.22%
Operating Cost Ratio	49.13%

The South region generated the highest revenue in the dashboard, while the East recorded the lowest. The net profit margin was 29.22%, and operating costs were equivalent to 49.13% of revenue. These results suggest that regional revenue differences and cost efficiency are useful starting points for further investigation; they do not, on their own, explain why the differences exist.

2 | Operational Performance Analysis

For the operational view, I compared device error rates and ERP response times by department. The average device error rate indicator was 5.02, and average ERP response time was 119.98 milliseconds. Treasury had one of the highest average response times, at approximately 121 milliseconds. The differences provide a way to identify

departments worth monitoring, although the device error rate unit still needs confirmation from the dataset definition.

3 | Risk & Compliance Analysis

The final page brings together fraud risk, compliance, and security-related activity. Average fraud risk was 50% on the dataset's score scale; this is not a claim that half of transactions were fraudulent. The average compliance score was 80.03, and the total recorded security breach attempts were approximately 85,000. North had the highest average fraud risk score, while the Risk department recorded the highest average compliance score at around 80.33.

What I would recommend

- Compare the strongest and weakest revenue regions in more detail before deciding on corrective action.
- Track operating costs alongside profit margin over time to identify changes in efficiency.
- Review departments with relatively higher device error indicators or ERP response times and investigate possible causes.
- Examine high-risk regions and departments with more recorded breach attempts, while distinguishing risk scores and attempts from confirmed incidents.
- Continue monitoring compliance scores and investigate departments with relatively lower results.

What this project demonstrates

This project helped me practice the full reporting workflow: preparing data, selecting appropriate calculations, building DAX measures, designing a consistent dashboard, and translating numbers into questions that a business team could act on. The result is an interactive report with three connected perspectives rather than three unrelated sets of charts.

Data note: This is a portfolio exercise based on a practice dataset, not verified results from a real organization. Values are shown as displayed in the report; some measurement definitions require confirmation.
